

Features of enzymes

1. High reaction rates: $10^6 - 10^{12}$ x or >) acceleration
2. Mild reaction conditions- water, low temp., low pressure, neutral pH
3. Reaction specificity
 - substrate (reactant), product
4. Capacity for regulation
 - substrates, products, metabolites, other proteins
 - allosteric control
 - covalent modification
 - enzyme synthesis

Rate acceleration vs.
noncatalyzed rate

$\sim 10^9$

$\sim 10^{10}$

$\sim 10^{14}$

$\sim 10^7$

Carbonic anhydrase

- One of simplest reactions catalyzed in nature
- Occurs nonenzymatically as well
- Why is CA catalysis so important?

Specificity

How do enzymes function

- Bring substrates together in correct orientation for catalysis
- Stabilize transition state of the reaction
- Facilitate bond breakage/formation
- Change the reaction mechanism (not always)
- Add intermediates to the reaction pathway

Binding energy, acid/base catalysis, charge stabilization, covalent catalysis, cofactor involvement

Strategies for enzymatic rate enhancement

1. Proximity/orientation
2. Weak interactions with substrate- “binding energy”
3. Structural flexibility
4. Transition state stabilization
5. General acid/base catalysis
6. Electrostatic interactions
7. Covalent catalysis

General principles of enzyme catalysis

1. Proximity- Enzymes can accelerate a rate simply by holding the two reactants close together in appropriate orientation
 - Intermolecular vs. intramolecular reactions
 - Translational, rotational and vibrational degrees of freedom
 - Enzymes are “entropy traps”

Intermolecular vs. intramolecular reactions

Formation of the ES complex:
thermodynamic considerations

$$\Delta G = \Delta H - T\Delta S$$

- proximity/orientation: decreases entropy
- noncovalent interactions of E and S: favorable enthalpy change

Binding energy: the energy derived from (noncovalent) enzyme-substrate interactions. The source of free energy to lower A_E of the reaction

Bimolecular reactions: spatial freedom, entropy, and enthalpy

What are units of k_{cat} for a unimolecular, bimolecular, or trimolecular reaction?

Enzymes as entropy traps: reactions become unimolecular upon binding of substrates

Effective molarity

The hypothetical concentration of one of the reactants of an intermolecular reaction that gives the same rate of reaction as the intramolecular reaction

Table 9.3 Relative Rates of the Esterification Reaction

$-\text{OH} + \text{HO}-\text{C}(=\text{O})-\text{OR} \longrightarrow -\text{O}-\text{C}(=\text{O})-\text{OR} + \text{H}_2\text{O}$		
Reactants	Rate constant $10^{-10} \text{ s}^{-1} \text{ M}^{-1}$	Effective concentration of intramolecular groups
		—
	$3.2 \times 10^{-6} \text{ s}^{-1}$	$3.2 \times 10^4 \text{ M}$
	$3.3 \times 10^{-6} \text{ s}^{-1}$	$3.3 \times 10^4 \text{ M}$
	$3.6 \times 10^{-5} \text{ s}^{-1}$	$3.6 \times 10^5 \text{ M}$
	$8.5 \times 10^{-2} \text{ s}^{-1}$	$8.5 \times 10^8 \text{ M}$

Rate constants for the uncatalyzed reactions in water from S. Milstien and L. A. Cohen, *Proc. Natl. Acad. Sci. USA* 67:1143-1147 (1970).

20

(b) Enzyme complementary to substrate

The enzyme active state should be more complementary to the structure of the transition state than to the structure of the substrate (or product)

(c) Enzyme complementary to transition state

Don't underestimate the importance of the weak interactions between enzyme and substrate!
(Jencks, the Circe Effect)

The rate acceleration for some enzymes is derived solely from binding energy

Active site residues and groups

- Weak interactions to stabilize/destabilize substrate, intermediates, transition state, product (**enthalpic role**)
- Functional groups involved in the reaction chemistry (**catalytic role**): transition state stabilization, changing reaction pathway

Roles of functional groups at the active site

Strategy: induce electron density changes in substrates/intermediates/transition states to facilitate bond cleavage and formation

general acids/bases

electrostatic interactions

covalent adducts

Roles of functional groups at the active site

Strategy: induce electron density changes in substrates/intermediates/transition states to facilitate bond cleavage and formation

general acids/bases

electrostatic interactions

covalent adducts

Example: ester hydrolysis

Note: showing the lone pairs of electrons on reactants, products, and intermediates is optional when drawing mechanisms

Transition state (TS) vs. intermediate (I)

- **TS:** dashed lines showing bonds forming/breaking
- **Intermediate:** Solid lines showing bonds resulting from the step involving the TS
- When drawing a mechanism, it is common not to show the transition states
- The electron pushing in a step represents the transition state involved in that step

Note: showing the lone pairs of electrons on reactants, products, and intermediates is optional when drawing mechanisms

S. Ensign principles of enzymatic catalysis

29

Transition state (TS) vs. intermediate (I)

S_N1 (dissociative)

S_N2 (associative)

S. Ensign principles of enzymatic catalysis

30

Functional groups: general acid/base catalysis

- make a potentially reactive group more reactive by increasing its intrinsic electrophilic or nucleophilic character via proton addition or removal
- **General acid:** A molecule other than water that serves as a proton donor
- **General base:** A molecule other than water that serves as a proton acceptor

S. Ensign principles of enzymatic catalysis

31

Acid-base Example: ester hydrolysis

Note: showing the lone pairs of electrons on reactants, products, and intermediates is optional when drawing mechanisms

Lower pK_a

Higher pK_a

Which amino acid is best suited to serve as a general acid/base at physiological pH values?

S. Ensign principles of enzymatic catalysis

33

Histidine serving as both a general acid and base (one base mechanism)

S. Ensign principles of enzymatic catalysis

34

Abbreviating general acids and bases when drawing reaction mechanisms (one base mechanism)

S. Ensign principles of enzymatic catalysis

35

Abbreviating general acids and bases when drawing reaction mechanisms: two base mechanism

S. Ensign principles of enzymatic catalysis

36

Examples we will look at in more detail where histidine functions as a general acid/base:

- Serine protease (hydrolase)
- Ribonuclease (phosphodiesterase)

Functional groups: electrostatic interactions

- Stabilize the distribution of electrical charge in transitions state(s) or high energy intermediate(s)
- A fixed charge interaction as opposed to proton transfer

Electrostatic interactions: Metal ion catalysis

- 1/3 of enzymes require a metal
- Roles:
 - Bind and orient substrate(s)
 - Mediate oxidation-reduction reactions
 - Electrostatically stabilize or shield negative charges

Charge stabilization vs. charge shielding

Metals can lower the pK_a of water

(Carbonic anhydrase mechanism)

Functional groups: Covalent catalysis

- Rate enhancement through the transient formation of enzyme-substrate covalent bond(s)
- Changes the reaction pathway to speed up the reaction (adds intermediate(s))
 - Increase substrate nucleophilicity
 - Increase substrate electrophilicity

Potential nucleophiles in enzymatic catalysis

Classic examples of covalent catalysis we will look at in more detail later (time permitting)

- Serine protease (hydrolase)
- Aldolase
- Glyceraldehyde-3-phosphate dehydrogenase

Potential electrophiles in enzymatic catalysis?

- No natural unmodified amino acids are good electrophiles
- A schiff base is a good electrophile and can be formed from lysine
- Some coenzymes are used as electrophiles (thiamine pyrophosphate, pyridoxal phosphate)
- Metal ions, as Lewis acids, can be good electrophiles

- Note importance of general acid/base catalysis

$$\text{H}_3\text{C}-\overset{\text{O}}{\parallel}\text{C}-\underset{\text{H}_2}{\text{C}}-\overset{\text{O}}{\parallel}\text{C}-\text{O}^- + \text{H}^+ \longrightarrow \text{H}_3\text{C}-\overset{\text{O}}{\parallel}\text{C}-\text{CH}_3 + \text{CO}_2$$

- S. Ensign principles of enzymatic catalysis*

- Carry out reaction in ^{18}O -labelled H_2O : acetone product has ^{18}O in carbonyl O

- Carry out reaction with acetoacetate labelled with ^{18}O in carbonyl O: no ^{18}O in acetone product

- Reduce enzyme during turnover with NaBH_4 : trap a covalent adduct w/K115

[illegible]

S. Ensign principles of enzymatic catalysis

Roles of functional groups at the active site

Strategy: induce electron density changes in substrates/intermediates/transition states to facilitate bond cleavage and formation

general acids/bases

electrostatic interactions

covalent adducts

Case studies that highlight principles of rate acceleration

- Tyrosyl-tRNA synthetase: all rate acceleration comes from binding energy!
- Serine proteases (e.g. chymotrypsin)
 - Binding energy, general acid/base catalysis, covalent catalysis, transition state stabilization
- Ribonuclease A
- Enzymes of glycolysis and the citric acid cycle (examples to be chosen based on lecture time remaining)

Why are enzymes big? Consider citrate synthase

Transition state theory

- Transition state analogs
- Catalytic antibody design

Why are enzymes big? (cont.)

- Define a specific active site
- Substrate channels
- Subunit interactions
- Regulatory control
- Membrane-bound?
- In vivo interactions (sequential reactions, multiprotein complexes)
